12 **Abstract.** Product development of today is becoming increasingly knowledge intensive.
13 Specifically, design teams face considerable challenges in making effective use of increasing
14 amounts of information. In order to support product information retrieval and reuse, one approach is
15 to use case-based reasoning (CBR) in which problems are solved “by using or adapting solutions to
16 old problems.” In CBR, a case includes both a representation of the problem and a solution to that
17 problem. Case-based reasoning uses similarity measures to identify cases which are more relevant to
18 the problem to be solved. However, most non-numeric similarity measures are based on syntactic
19 grounds, which often fail to produce good matches when confronted with the meaning associated to
20 the words they compare. To overcome this limitation, ontologies can be used to produce similarity
21 measures that are based on semantics. This paper presents an ontology-based approach that can
22 determine the similarity between two classes using feature-based similarity measures that replace
23 features with attributes. The proposed approach is evaluated against other existing similarities.
24 Finally, the effectiveness of the proposed approach is illustrated with a case study on
25 product-service-system design problems.
26

1 **1. Introduction**

2 Due to the complexity of products, product development is becoming increasingly knowledge
3 intensive. Design is also multi-disciplinary in nature requiring a variety of product life-cycle
4 knowledge [1]. Specifically, design teams face a considerable challenge in making effective use of
5 increasing amounts of information that often accumulate and remain in isolated information systems.
6 Also, it is often the case that product designers can reuse past designs rather than designing from
7 scratch [2].

8 Information retrieval consists of translating and matching a query against a set of information
9 objects. Translation of the query is necessary for converting the user requirements into the language
10 provided by the information retrieval system. The information retrieval system responds to the query
11 using a given algorithm and a similarity measure. Particularly, information retrieval plays an
12 important role in areas such as product family design [3], product embodiment, and detailed design
13 [4]. Shah et al. [5] present a combination framework that consists of software engineering, data
14 engineering and knowledge engineering and design theory.

15 In order to support product information retrieval and reuse, some authors suggest the use of
16 case-based reasoning (CBR) in which design problems are solved by using or adapting previous
17 design solutions [4], [6].

18 A CBR system is composed of domain knowledge, a case base, and a search mechanism based on
19 a similarity measure. Domain knowledge refers to knowledge about the features of the different
20 objects or entities that a case is about. A case base contains a set of cases, each of which describes a
21 problem and a solution to the problem. The problem is typically defined in terms of specific features
22 of objects. Finally, a similarity measure quantifies the differences that exist between objects [7]. CBR
23 uses similarity measures to identify cases which are more relevant to the problem to be solved.

24 Most similarity measures evaluate differences between values of numeric properties such as in
25 the numerical difference between two given diameter values. However, many applications also

1 require non-numeric similarities. For example, case-based reasoning systems for the conceptual
2 design of products must be developed to work with a limited knowledge about the product.

3 Nearly all of non-numeric similarity measures are based on syntactic grounds. For example, the
4 Levenshtein distance [8], [9] can be used to calculate the similarity between two words, in terms of
5 the minimum number of operations that are needed to transform one of the words into the other.
6 However, from the point of view of the meaning of the words that are compared, existing syntactic
7 similarity-measures often result in incorrect matches.

8 Semantic similarity measures can be used in order to overcome the limitations of syntactic
9 approaches. A semantic similarity is a function that assigns a numeric value to the similarity between
10 two classes of objects based on the meaning associated to each of the objects [10]. For a review of
11 semantic similarity metrics, the reader is referred to the paper of Cross and Hu [11].

12 Recently, the use of ontologies for evaluating similarity has been reported in the literature [12],
13 [13]. Ontologies are formal models that use mathematical logic to disambiguate and define classes of
14 things [14]. Specifically, ontologies describe a shared and common understanding of a domain in
15 terms of classes, possible relations between things, and axioms that constrain the meaning of classes
16 and relations [15]. A class represents a set of things that share the same attributes. A relation is used
17 to represent a relationship among two or more things. Examples of relations are less than, connected
18 to, and part of. Class taxonomies are defined by means of the subclass relation. A class is a subclass
19 of another class if every member of the subclass is also a member of the super class. Axioms are
20 typically represented as logic constructions that formally define a given class or relation.

21 Combined with automated reasoning applications, ontologies can be used for several purposes
22 such as knowledge extraction and information retrieval. Unfortunately, ontologies are typically
23 created in an ad-hoc manner, which may influence the accuracy of the similarity calculations.

24 Formal concept analysis (FCA) is a data processing method that can be used to design ontologies
25 [16] [17]. FCA is based on a set of objects and a set of attributes. In this paper, we use FCA along

1 with a theoretical framework for developing product and process ontologies.

2 Most semantic similarities are defined in terms of the number of edges between the classes that
3 they compare (edge-counting similarity measures). Other semantic similarities are defined in terms
4 of features but use synsets for the comparison between words rather than classes.

5 The underlying thesis in this paper is that if a class represents a set of things that share the same
6 attributes (such as a class in an ontology), we can state that a class is equivalent to another class if
7 both classes have exactly the same attributes. This implies that the more common attributes that are
8 shared by two classes the more similar they are. In this paper, we show how an ontology-based
9 approach can determine the similarity between two classes using feature-based similarity measures
10 that replace features with attributes.

11 The paper is organized as follows. Section 2 describes the theoretical framework used in this pa-
12 per. Section 3 provides details on the ontology development. Section 4 describes the proposed on-
13 tology-based similarity measures. Sections 5 and 6 describe the evaluation of the semantic measures
14 proposed in this paper. In section 7, the effectiveness of the proposed approach is illustrated with a
15 case study on product-service-system design problems. Section 8 discusses some related work and
16 section 9 presents conclusions and suggestions.

17

18 **2. Theoretical framework for product representation**

19 Theoretical frameworks for product representation refer to the world view with which product
20 information models or ontologies can be developed in order to represent a product. In this paper, the
21 theoretical framework for representing a product is based on the ISO 15926 standard which specifies
22 an upper ontology for long-term data integration, access and exchange [18]. It was developed in ISO
23 TC184/SC4-Industrial Data by the EPISTLE consortium (1993-2003) and designed to support the
24 evolution of data through time. The upper ontology was developed as a conceptual data model for
25 the representation of technical information of process plants including oil and gas production facili-

1 ties but it was designed to be generic enough for any engineering domain [19].

2 In this theoretical framework, the device is represented in terms of its physical aspects as well as
3 in terms of its relation to some process (*activity* in ISO 15926). These aspects are illustrated in the
4 models of Fig. 1 and Fig. 2.

5 A device is represented as a physical object that is defined in terms of a distribution of matter,
6 energy, or both. The device is also described in terms of its parts. This is possible through a mereo-
7 logical relation that refers to the relationship that a part has in regards to the whole of an object.
8 Mereological relations are reflexive, antisymmetric, and transitive.

9 Physical objects exist in reference to a specific place. The location relation (*relative location* in
10 ISO 15926) is a kind of mereological relation that is used to locate objects in a particular place.

11 A stream is another kind of physical object that is applied to material or energy moving along a path,
12 where the path is the basis of identity and may be constrained. For example, the material moving
13 along a pipe is an instance of stream.

14 The function of a product can be defined as an intended process associated to the device. For
15 example, the function associated to a sofa is represented as the process of seating in which the sofa is
16 involved along with a person that sits on it. Similarly, the function of an electric fan is to generate
17 cool air. In this case, the description of the device includes information about the cooling process.
18 The cooling process is in turn composed of other processes such as conversion of electricity into ro-
19 tary movement, convection, diffusion and heat transfer. Therefore information about the process or
20 processes associated to the device is an indispensable element to complete the description of the
21 product.

22 Different objects can participate in a process. Participating physical objects include those objects
23 that are transformed by the process, those objects that are produced by the process, those objects that
24 are not affected by the process (the device itself, other tools, or instruments), as well as agents (such
25 as a person or a control system) that participate or execute the process.

1 As in the description of the device, a process is also described in terms of its relative location and
2 its mereology.

3 **3. Ontology construction**

4 There are a number of methodologies to develop ontologies including Uschold and King's
5 method [25], Grüninger and Fox's method [26], Noy and McGuinness's method [27], the
6 METHONTOLOGY framework [28], the Cyc methodology, KACTUS, SENSUS, and the
7 On-To-Knowledge Methodology [29].

8 According to Stevens et al. [30], the general stages for ontology development are: identification
9 of purpose and scope, knowledge acquisition, conceptualization, integration, encoding,
10 documentation, and evaluation. We follow these general steps, but we use FCA (see Appendix 1) and
11 the theoretical framework described in Section 2 to guide the knowledge acquisition and
12 conceptualization stages.

13 Candidate classes that may or may not appear in the final ontology are identified, and the object
14 column of a FCA context table is populated with these classes.

15 Subsequently, information sources such as scientific papers, technical reports, and Internet
16 resources are consulted to define each class in natural language. When several definitions are found
17 preference is given to those that explicitly describe participating objects, objects transformed by the
18 process (inputs), objects produced by the process (outputs) and/or subactivities. When contradictions
19 among several definitions of a given class occur experts can be consulted to disambiguate.

20 Formal attributes are identified from the natural-language definitions using the following guide-
21 line.

22 A device (a physical object) is characterized by:

- 23 1. The process in which the device participates.
- 24 2. The composition of the device (its parts).

25 In turn, a given process or the process in which the device participates is characterized by the

1 following:

- 2 ■ The object that is transformed by the process (the input of the process).
- 3 ■ The object that is produced by the process (the output of the process).
- 4 ■ The tool that is present in any instance of the process.
- 5 ■ The composition of the process.

6 After adding the formal attributes, the context table is completed and a lattice is
7 generated. Lattices in this paper were generated by means of the Grail algorithm [24],
8 which is implemented in the software Concept Explorer. Finally, the lattice is used to create
9 the ontology. The naming of each class is done based on object or attributes labels from the nodes in
10 the lattice.

11 Integration is carried out by means of aligning the resulting ontology with an upper ontology that
12 defines domain-independent classes such as physical objects, activities, mereological and topological
13 relations. For example, a class refrigerator is defined as a subclass of *physical_object*, which is a
14 class of the ISO 15926 upper ontology.

15

16 **4. Ontology-based semantic similarities**

17 In a given ontology, a class is equivalent to another class if both classes have exactly the same
18 attributes². Therefore, the more common attributes that are shared by two classes the more similar
19 they are.

20 The proposed approach consists of combining feature-based similarities with an ontology
21 obtained with the procedure described in Section 3 and using formal attributes from the FCA as
22 features. The feature-based similarities investigated in this paper are: the Tversky index [21], the
23 Dice's coefficient [22], the Jaccard's coefficient [31], the Overlap coefficient [23], the all-confidence
24 similarity [23], and the Cosine similarity.

² The attributes of a class also include those attributes inherited from its parent classes.

1 For example, Tversky index becomes:

$$2 \quad \text{sim}_{Tversky}(C_1, C_2) = \frac{|A_1 \cap A_2|}{|A_1 \cap A_2| + \alpha|A_1 \setminus A_2| + \beta|A_2 \setminus A_1|} \quad (1)$$

3 where α and β are parameters calculated according to Rodriguez and Egenhoffer [32], A_1
4 and A_2 are the sets of attributes of classes C_1 and C_2 , $|A_1 \cap A_2|$ is the total number of formal
5 attributes shared by C_1 and C_2 , $|A_1|$ and $|A_2|$ represent the number of formal attributes of C_1
6 and C_2 .

7 We also use the similarity equations given by van der Weken et al. [33] but using formal attribute
8 sets instead of fuzzy sets:

$$9 \quad \text{sim}_{vanDerWeken1}(C_1, C_2) = \frac{|A'_1 \cap A'_2|}{\min(|A'_1|, |A'_2|)} \quad (2)$$

$$10 \quad \text{sim}_{vanDerWeken2}(C_1, C_2) = \frac{|A'_1 \cap A'_2|}{\max(|A'_1|, |A'_2|)} \quad (3)$$

11 where A_1 and A_2 are the sets of attributes of classes C_1 and C_2 ; and A'_1 and A'_2 are the
12 complements of sets A_1 and A_2 .

13 No restriction exists for one of the classes to be a subclass or a superclass of the other. In other
14 words, the classes to be compared can happen anywhere in the ontology.

15 In addition, we also investigate a composite similarity obtained by combining semantic
16 similarities:

$$17 \quad \text{sim}_{Composite}(C_1, C_2) = w_1 \text{sim}_1 + w_2 \text{sim}_2 \quad (4)$$

18 where w_1 and w_2 are weights and sim_1 and sim_2 represent two different semantic
19 similarity measures.

20 In order to compare against edge-counting similarity measures, calculations are also carried out
21 using both Wu-Palmer's [20] and Lin's [10] similarity measures.

22 **5. Experimental evaluation of the proposed approach using human judgment**

1 This experiment focuses on the domain of electric home appliances for the evaluation of different
 2 semantic similarities. The evaluation is carried out by measuring the degree of correlation between
 3 the calculated similarity scores and scores obtained by human judgments. For this purpose, a ques-
 4 tionnaire was administered to 30 respondents. The questionnaire asked each respondent to rank the
 5 likeness between ‘electric kettle’ and each of 17 home electric appliances. Respondents then rated the
 6 similarity of the pairs on a 1-17 scale, with lower numbers indicating higher similarity.

7 The comparison was carried out by calculating the correlation coefficient and the sum of squared
 8 errors.

9 The level of inconsistency of each questionnaire was calculated with the following formula.

$$10 \quad d_i = \sum_j |q_{ij} - \mu_{ij}| \quad (5)$$

11 where q_{ij} is the value of the score that participant i submitted for pair j and μ_{ij} is the mean of the
 12 scores of all the users except that of user i for pair j . Using this formula, questionnaires with values
 13 of d_i above two standard deviations from the mean \bar{d}_i were excluded from the analysis.

14 The average standard deviations of the scores across respondents were also evaluated to identify
 15 inconsistencies. Since one of the questionnaires had a standard deviation lower than average, it was
 16 not taken into account. With this last change, the sample size was reduced from 30 to 27.

17 Finally, individual pair scores with one standard deviation below or above the pair mean \bar{q}_j
 18 were eliminated, which accounted for 4% of the total data.

19 Subsequently, the average scores were normalized using the following transformation:

$$20 \quad s_j = \frac{\bar{q}_j - q^{\min}}{q^{\max} - q^{\min}} \quad (6)$$

21 where s_j represents the similarity of pair j , $q^{\max} = 17$ and $q^{\min} = 1$. Values of s_j are shown
 22 in the first column of Table 1.

23 **5.1 Ontology development**

1 In this section, we describe the development of an electric home appliance ontology, which is
2 based on the method described in section 3. The list of potential classes was extracted from product
3 categories in Amazon.com and the attribute information was obtained using the characterization
4 explained in Section 3, using expert consultations and brainstorming. In the development of the
5 ontology, we focused on the process or processes in which the given appliance participates or is
6 involved. Therefore, formal attributes include a reference to the process or a description of the
7 process in terms of the objects that are transformed by the process and the objects that are produced
8 by the process. For example, the formal attribute identification of an electric kettle starts by the
9 analyzing its main process associated to it, which is a process that produces hot water. Heating is a
10 part of that process. In order to produce hot water, the electric kettle consumes electricity that is
11 converted into thermal energy that is used to heat water. Therefore, the formal attributes of an
12 electric kettle become ‘heats’, ‘produces hot water’, ‘heats water’, and ‘consumes electricity’.

13 With formal-attribute information obtained this way, a context table was created (Fig. 3).
14 Subsequently, Concept Explorer [24] was used to generate the concept lattice shown in Fig. 4. After
15 analyzing and correcting the lattice, the final lattice and formal-attribute information were used to
16 develop an ontology using the Protégé ontology editor [34]. Subsequently, the resulting ontology was
17 saved in OWL format [35].

18 Strictly speaking, formal attribute information must be in the form of axioms as in the following
19 example.

```
20 Class filtration:  
21   SubClassOf:  
22     heating_device  
23   SubClassOf:  
24     produces some hot_water  
25
```

26 However, for simplicity in the similarity calculation, formal attributes were added as OWL
27 properties. For example, the formal attribute for “produces hot water” is declared as follows:

```
28 Declaration( ObjectProperty( :produces_hot_water) )  
29 ObjectPropertyDomain(:produces_hot_water :water_heater)
```

1
2 This resulted in an OWL file with 33 classes, 39 properties, and 5 levels in the class hierarchy.

3

4 **5.2 Similarity calculation**

5 A program was developed in Java using the ontology library Jena [36]. The program reads the
6 ontology and the names of the two classes to be compared. Firstly, it extracts the formal attribute
7 information of each class in the ontology. Then, the program proceeds to calculate the cardinalities
8 for each set of attributes, the minimum and maximum values, and the number of overlapped
9 attributes. Attributes of a class include those inherited from all its parent classes. Similarity
10 calculations are then carried out using the feature-based similarities as explained in Section 4. Then
11 the Wu-Palmer's and Lin's similarities are calculated by edge counting, using the taxonomy structure
12 of the ontology.

13

14 **5.3 Experiment results**

15 Table 1 summarizes the calculation results of the investigated similarities rating between 17 class
16 comparisons.

17 We introduced 'device' as subclass of *physical_object* (defined in ISO 15926) and made 'home
18 electric appliance' a subclass of 'device'. From Table 1, it can be seen that the best performing
19 similarity is the Overlap coefficient ($sim_{Overlap}$) with $R=0.795$ followed by the Wu-Palmer similarity
20 with $R=0.782$, the Cosine similarity (sim_{Cosine}) with $R=0.781$, and Dice's coefficient with (sim_{Dice})
21 with $R=0.777$.

22 After considering every possible combination of feature-based similarities for the composite
23 similarity equation of Equation (4), the best two combinations were:

$$24 \quad sim_{Cosine+Jaccard}(C_1, C_2) = 1.887sim_{Cosine} - 0.887sim_{Jaccard} \quad (7)$$

25 with a correlation of $R=0.817$ and

$$26 \quad sim_{Dice+Jaccard}(C_1, C_2) = 1.966sim_{Dice} - 0.966sim_{Jaccard} \quad (8)$$

1 with a correlation of $R=0.816$.

2 The weights w_1 and w_2 were obtained by numeric optimization so as to minimize the residual
3 sum of squares between the composite similarity and s_j of Equation (6).

4

5 **5.4 Analysis of the results**

6 To eliminate biases in the analysis of the results, we removed those pairs that produced squared
7 errors greater than two times the standard deviation. The pairs (electric kettle, television set) and
8 (electric kettle, electric oven) produced the biggest squared error. After removing both pairs, the
9 correlation value of the Overlap coefficient increased to $R=0.947$. Again, $\text{sim}_{\text{Cosine}}$ ($R=0.922$) and
10 sim_{Dice} ($R=0.919$) were second and third in performance, respectively. For the combined
11 similarities, $\text{sim}_{\text{Cosine+Jaccard}}$ increased to $R=0.950$ and $\text{sim}_{\text{Dice+Jaccard}}$ increased to $R=0.947$.

12 A hierarchical cluster analysis was conducted in order to compare relatively homogeneous
13 groups of results. The cluster analysis was equally applied to both the human assessment results and
14 the results obtained with the Overlap coefficient. Clustering was carried out using Ward's minimum
15 variance algorithm.

16 A comparison of the clusters indicates that most of the object pairs that belong to one cluster with
17 the Overlap coefficient also belong to a cluster in the results of human judgment. As shown in Fig. 5,
18 only (electric kettle, television set), (electric kettle, air conditioner), and (electric kettle, bread
19 machine) were grouped into another cluster. This is probably due to missing attributes in the FCA
20 context table. Alternatively, another possible reason is that these three pairs were particularly
21 difficult to judge during the answering of the questionnaire.

22

23 **6. Experimental evaluation of the proposed approach using Web search**

24 This experiment uses the Web to evaluate the different similarity measures. In order to increase
25 the accuracy of the Web-based evaluation, a more technical domain was selected. For this reason, we

1 chose machining processes as the technical domain. Moreover, the evaluation was carried out with
2 the search engines provided by Google's Scholar and Elsevier's Scirus.

3 Despite the existence of a vast variety of machining processes, in order to obtain a compact on-
4 tology, the scope of this experiment was limited to mechanical material removing processes. In order
5 to develop the ontology, several common textbooks [37], [38] [39], [40], [41] and an Internet source
6 [42] were consulted. The potential classes are listed in the first column of Table 3.

7 During the construction of the ontology, in order to determine the formal attributes for the con-
8 text table, all the material removing processes were characterized according to the process character-
9 ization explained in Section 3.

10 Fig. 6 shows the context table with the classes of material removing processes. The resulting
11 concept lattice is presented in Fig. 7. The similarity measures were the same as in the experiment of
12 Section 5. The above mentioned Java program was used in all the calculations.

13 This time, the resulting similarity scores were compared against the Web-based similarity denot-
14 ed by equation (9).

$$15 \quad v(t_i, t_j) = 1 - d(t_i, t_j) \quad (9)$$

16 where $v(t_i, t_j)$ is the Web-similarity of terms t_i, t_j , and $d(t_i, t_j)$ represents the distance function pro-
17 posed by Cilibrasi and Vitanyi [43] also known as the normalized Google distance or NGD. The dis-
18 tance function of Cilibrasi and Vitanyi is described by equation (10).

$$19 \quad d(t_i, t_j) = \frac{\max(\log f(t_i), \log f(t_j)) - \log f(t_i, t_j)}{\log M - \min(\log f(t_i), \log f(t_j))} \quad (10)$$

20 where $f(t_i), f(t_j)$ and $f(t_i, t_j)$ give the number of hits for the terms t_i, t_j and (t_i, t_j) respectively. M
21 corresponds to the number of indexed documents in a given Web search engine. The number of in-
22 dexed documents of Scirus which is reported on its Web page is 4.6×10^8 as of May 21, 2012. A value
23 of $M = 5.8 \times 10^8$ for Google Scholar was obtained from an earlier estimate [44] and by assuming a
24 growth rate of 2.7% based on the world-wide average annual increase of academic papers [45].

25 In order to restrict the Web search to the domain of study, keywords in both search engines were

1 formulated with the inclusion of the term “machining” and search was carried out using double
2 quotes.

3 For example, for the similarity between counterboring and spot facing, search with Scholar for
4 “machining” “counterboring” results in $f(\text{counterboring})=1019$ hits; search for “machining” “spot
5 facing” produces $f(\text{spot facing})=620$ hits; and search for “machining” “counterboring” “spot facing”
6 results in $f(\text{counterboring, spotfacing}) = 56$ hits. Substituting these values in Equation (10) gives
7 $d(\text{counterboring, spotfacing}) = 0.2146$. Using Equation (9) we obtain $v(\text{counterboring, spot facing}) =$
8 0.7854 .

9 Calculations were carried out for pairwise similarities between all the pairs of processes, result-
10 ing in 45 comparisons. Table 2 summarizes the results of the calculations.

11 The best single similarity measure was the van der Weken similarity ($sim_{vanDerWeken2}$) with
12 correlation coefficients of $R=0.828$, and $R=0.916$, for Scirus and Scholar respectively. Then, the
13 Jaccard’s coefficient ($sim_{Jaccard}$) came up second.

14

15 **7. Case Study**

16 In this case study we focus on the effectiveness of the ontology-based semantic similarities in the
17 context of product-service system (PSS) design. A PSS is a mix of both products and services that is
18 often associated to better sustainability. In the design of PSS systems, one common design decision
19 is the selection of the type of service that can be integrated with a given product [6].

20 A CBR system was developed in Java by extending the open source software FreeCBR. As in
21 any traditional CBR system, each case is defined in terms of a problem and a solution. In this case
22 study, the problem is defined in terms of case features that represent characteristics of a given
23 product. The case features can be numeric or semantic. For numeric features, the index approach
24 proposed by Lin et al. is used [6]. The semantic feature is specified as the class to which the product
25 belongs, that is defined in a product ontology. The similarity for such semantic feature was

1 calculated using the Overlap coefficient and the formal attributes of each class. A screen dump of the
 2 CBR system is shown in Fig. 8.

3 The case similarity in the CBR system is calculated using the equation proposed by Kolodner and
 4 Simpson [46]:

$$5 \quad S(t,r) = \frac{\sum_{i=1}^n w_i \times \text{sim}(f_i^t, f_i^r)}{\sum_{i=1}^n w_i} \quad (11)$$

6 where $S(t,r)$ is the global similarity between the target case t and a source case r ; w_i is
 7 the weight of feature i ; f_i^t is the value of feature i of target case t ; and f_i^r is the value of
 8 feature i of a source case r .

9 $\text{sim}(f_i^t, f_i^r)$ is calculated according to the following criteria, which is based on the Overlap
 10 coefficient and a similarity for numerical attributes.

$$11 \quad \text{sim}(f_i^t, f_i^r) = \begin{cases} \frac{|A_i^t \cap A_i^r|}{|A_i^t \cup A_i^r|} & \text{if } f_i^t \text{ and } f_i^r \text{ are categorical} \\ \frac{\min(f_i^t, f_i^r) - f_i^{\min}}{f_i^{\max} - f_i^{\min}} & \text{if } f_i^t \text{ and } f_i^r \text{ are numerical} \end{cases} \quad (12)$$

12 where A_i^t is the set of formal attributes of the class specified in feature f_i^t ; A_i^r is the set of formal
 13 attributes of the class specified in feature f_i^r ; and f_i^{\max} and f_i^{\min} are the maximum and minimum
 14 numeric values of feature f_i respectively.

15
 16

17 **7.1 Ontology development**

18 A product ontology was developed based on the procedure described in Section 3 and using the
 19 list of products reported in [6]. The resulting concept lattice is shown in Fig. 9. The product ontology
 20 extends the upper ontology defined in the ISO 15926 standard [15]. To carry out the alignment, three
 21 classes were added as subclasses of *physical object*: substance, mixture, and device based on [47].

22 During the preparation of the FCA context table, attributes were selected by investigating the
 23 process or processes in which the product participates or is involved. Each process was described

1 according to the process characterization explained in Section 3. For example, the objects that are
2 transformed during the operation of a copier are the data input by the user, electricity, and paper and
3 the objects that are produced by the same process are the copied printed paper. Thus, the attributes of
4 the copier become: consumes data, consumes electricity, consumes paper, and produces printed
5 paper.

7 7.2 Experiment setup

8 The case base was populated with information about 47 successful product services systems.
9 Each case was described in terms of numerical and semantic features. Based on [6], the following
10 numeric features and weights were used: place of usage of the PSS system ($w_1 = 0.116$), frequency
11 of usage of the PSS system ($w_2 = 0.232$), product fashion cycle ($w_3 = 0.042$), product volume
12 ($w_4 = 0.036$), product weight ($w_5 = 0.034$), product useful life ($w_6 = 0.064$), product price
13 ($w_7 = 0.082$), subsequent expenditure ($w_8 = 0.116$), GDP per capita ($w_9 = 0.119$), population
14 density ($w_{10} = 0.079$), area of territory ($w_{11} = 0.052$), and temperature range of the territory
15 ($w_{12} = 0.059$). The allowable values for each numeric feature and their meaning is also explained in
16 [6]. For example, the index used to describe the place of usage of the PSS system is defined for inte-
17 ger values ranging from 1 to 3, where 1 represents indoor, 3 outdoor and 2 both. Among these fea-
18 tures, product fashion cycle, volume, weight, useful life, and price are product features. The objec-
19 tive of this experiment was to evaluate the possibility of using a semantic feature as a replacement of
20 some of the product attributes. The semantic feature consisted of the class of product defined in the
21 product ontology.

22 Initially, two experiments were carried out. The objective of experiment 1 was to provide a ref-
23 erence for comparing the proposed approach. For this purpose, all the queries in experiment 1 con-
24 sisted of values for all the numerical features without the semantic feature.

25 In experiment 2, queries were formulated by replacing two product features (product volume and

1 product weight) by the corresponding class of product from the ontology. The weight for this seman-
2 tic feature was set to $w_{13} = 0.07$.

3 The case similarity in both experiments were calculated with equations (11) and (12).

4 The queries were formulated with the product information from each of the cases stored in the
5 case base. Therefore, 47 problems were defined with the problem data of the 47 cases in the case
6 base, resulting in a total of 94 experiments. The objective was to find the service strategy and then
7 compare the result with the already known service strategy of the corresponding case. For example,
8 problem 1 describes a certain kind of washing machine that was used in PSS that provided a repair
9 service. In this example, it is thus expected that all if not most of the n best matches return repair as
10 the solution.

11 The execution of each query resulted in a ranked list of matches each of which included product
12 information, the proposed service strategy, and a global similarity value. Then the resulting service
13 strategies were compared against the original service. Table 3 shows the results for both experiments.
14 The best five matches are shown for each problem. From the overall results, it can be observed that
15 there are 9 problems (Nos. 1, 5, 10, 14, 18, 26, 28, 43 and 45) in which the results of experiment 1
16 are identical with those of experiment 2. For example, the best five service strategies in problem 1
17 were: refrigerator-repair, computer-repair, water heater-repair, laser printer-repair and LCD moni-
18 tor-repair, all of which are consistent to the repair service corresponding to the solution of problem 1.

19 Other problems produced slightly different results. For example, in experiment 2, problems 11,
20 12, 19, 20, 33, 34, 37, 38, 40, 41 and 42 produced the same five best matches found in the results of
21 experiment 1 but with a different ranking. For example, in problem 11 both experiments resulted in
22 treadmill-lease, dryer-lease, LCD TV-lease, refrigerator-lease and dish washer-lease. However, while
23 treadmill-lease has the highest rank in experiment 1, it appears second in experiment 2.

24 In addition, there were 27 results (such as problems 2, 3, 4, 6, 7, 8, and 9) that differed in one or
25 two cases. For example, the results for problem 2 include an Internet-based digital calendar which is

1 false positive. On the other hand, some results of experiment 2 were good matches albeit being
2 missing in experiment 1. For example, (sofa-lease and platform bed-lease instead of jewelry-rental
3 and handbag rental) in problem 9 are good matches.

4 Furthermore, the results of experiment 2 for problems 30 (photocopy-service), 31 (scan-
5 ning-service) and 32 (laminating-service) are better when compared to the results of experiment 1 in
6 which not only the best 5 matches refer to a service that equals that of the case from which the query
7 was formulated (pay per service unit) but also the product is more compatible with that of the sug-
8 gested service. For example, experiment 2 for problem 30 resulted in laundry-service, print-
9 ing-service, eyeglass cleaning-service, scanning-service and fax-service. Among these, printing,
10 scanning and fax can be carried out with a copier machine. These results contrast with those obtained
11 with experiment 1 which included cleaning-service, eyeglass cleaning-service and shoes cleaning
12 service.

13 In order to corroborate the influence of the semantic similarity, an additional experiment was
14 conducted (experiment 3). Experiment 3 excluded the numeric product features of volume and
15 weight as well as the semantic feature. For this evaluation, we counted the cases in the best five re-
16 sults that were common to those in experiment 1. In other words, the ideal number of common cases
17 is 5. These results are summarized in Table 4. The presence of the semantic similarity measure in
18 experiment 2 resulted in an average of 4.32 common cases, while its absence in experiment 3 result-
19 ed in an average of 3.79. This means that in the absence of data for product volume and weight, the
20 use of the semantic feature shows an improvement of almost 14% compared to not using it. From
21 this, it can be concluded that ontology-based semantic similarities have the ability to emulate (at least
22 to some extent) the numeric product features.

23

24 **8. Related work**

25 Several efforts are reported on the use of ontologies in product design. One interesting exam-

1 ple is the work of Patil et al [48] who describe an ontology that is based on definitions from the
2 NIST's Core Product Model. They describe a methodology for building artifact ontologies which is
3 based on the identification of subclasses of artifact, feature, assembly, and other classes. In the on-
4 tology development process, each artifact is characterized in terms of its form, function, and behav-
5 ior (the implementation of the function).

6 Annamalai et al. [49] define a general framework for product-service systems that is facilitated
7 by means of an ontology. The terminologies and semantics are based on 8 top-level classes that cover
8 product life cycle and the supporting elements such as stakeholder involvement. The ontology is de-
9 veloped using findings from literature review and the opinion of domain experts.

10 In the area of product customization, Tseng et al. [50] present a CBR system to support con-
11 ceptual product design. In their work, a numeric similarity measure is combined with part-whole in-
12 formation that has a tree representation. Another similar work is that of Cobb and Agogino [51] who
13 developed a CBR system for designing Micro-Electro-Mechanical Systems (MEMS). They discuss
14 the results of a case-retrieval experiment in which MEMS are described in terms of functional and
15 structural features. These features are numeric, which suggest that case retrieval is carried out by
16 means of a numeric similarity.

17 In an attempt to generate new product ideas, Wu et al. [52] propose a CBR system in which a
18 product is represented as a numeric vector consisting of 87 elements. Each element represents a
19 product attribute. The product attributes are organized into five dimensions: interface modality, task,
20 physical feature, environment, and users. Some of the attributes in the interface modality resemble
21 the use of the participation relation defined in ISO 15926 such as specifying the parts of the body
22 involved in [the use of] a given product. The task dimension represents the tasks to be performed by
23 the user through the use of the product. Attributes in this dimension are equivalent to specific pro-
24 cesses associated to a product. The physical dimension is for attributes such as product sizes. Envi-
25 ronment includes attributes such as indoor or outdoor places. Finally, attributes in the user dimension

1 characterize the user in terms of gender, age, etc. Every attribute in the product vector requires a
2 value that represents the relevancy to that attribute.

3 Lin et al. [6] propose the use of CBR to support the design of product service systems (PSS).
4 Specifically, their CBR selects service strategies for a given product. A case is described in terms of
5 12 features which are grouped into three categories, namely, user behavior, product, and environ-
6 mental environment. User behavior is specified in terms of place of usage, and frequency of usage.
7 The product is specified in terms of features describing its fashion cycle, volume, weight, useful life,
8 price, and subsequent expenditure. External environment is defined in terms of GDP per capita, pop-
9 ulation density, area of territory, and temperature range. Each feature is quantified using integer val-
10 ues. The case similarity is obtained by using a weighted summation of all the feature similarities. The
11 weights are determined by means of the Analytic Hierarchy Process (AHP).

12 In the area of Web services, Bramantoro et al. [13] propose a similarity measure that quantifies
13 the semantic distance between classes in an ontology of the products that are delivered by the ser-
14 vices. Their work is motivated by limitations of other approaches in which only certain super-
15 class-subclass links were taken into account. Their approach was based on the path length, number of
16 downward edges counted between two classes, and the number of common closest ancestors. It is
17 interesting to note that despite the fact that some semantic measures already existed they were ap-
18 parently unknown in that domain.

19

20 **9. Conclusions**

21 This paper presented ontology-based semantic similarity measures that determine the degree of
22 likeness between two classes. The main distinguishing aspect of the proposed approach is the use of
23 ontologies obtained with FCA coupled with feature-based similarities. Results of the numeric
24 experiments showed that in all cases, the proposed semantic measures performed better than the
25 similarities of Wu Palmer and Lin.

1 In the electric appliance experiment, after removing the least performing pairs (electric kettle,
2 television set) and (electric kettle, electric oven), the correlation saw an increase of approximately
3 25%. The reason might be that both television set and electric oven were characterized by processes
4 which are unfamiliar to the common user. For example, toaster was characterized as a device that
5 uses infrared radiation. In this case, infrared radiation was considered as a part of heating, which is
6 directly related to toasting bread. Similarly, TV set was defined as a device that receives television
7 signals.

8 When other devices were characterized in terms of processes and participating objects that were
9 more familiar to the common user, the calculated similarities were close to the human judgments.
10 However, albeit important to the designers, from a user point of view, subprocesses that are not
11 directly perceived by the users (i.e. the mechanism with which a product achieves its given function)
12 are probably not taken into account. This could be a limitation of the questionnaire approach for
13 evaluating the similarities.

14 A CBR system for Product Service Systems demonstrated the effectiveness of the proposed sim-
15 ilarity measures. In the CBR case study, the combination of the ontology and the semantic similarity
16 proved useful when some details such as weight and volume are not available. Therefore, the de-
17 signer can be relieved by needing less data to define a given design problem, which is particularly
18 important during the conceptual stage of the design.

19 Nevertheless, in a few instances the proposed approach resulted in mismatches. This could be due
20 to the lack of attributes in the FCA context table. For example, the addition of attributes that empha-
21 size the difference between software and hardware products could reduce the number of false posi-
22 tives for problem 2.

23 A key element in the proposed approach is the use of FCA. From an information modeling point
24 of view, the use of formal concept analysis is useful but the development of the context table has a
25 large degree of freedom. Specifically, the selection of attributes in the context table of the FCA

1 analysis plays an important role. Therefore, the selection of attributes should be based on an explicit
2 guideline. In this paper, the attributes were selected based on the assumption that every product
3 performs or is-involved-in processes (or activities using the ISO 15926 terminology). Therefore,
4 subclasses of *physical object* are characterized not only by the mereology of the objects, but also by
5 the processes associated to them. A class of process is in turn characterized in terms of the objects
6 that are transformed (inputs), objects that are produced (outputs), other participating objects, and the
7 mereology of the process.

8 Finally, the results of the correlation between the different semantic similarities and human
9 judgment or Web-based search suggest that multiple similarity measures can be used as a way to
10 validate ontologies. The reason is that the accuracy of the ontology directly influences the correlation
11 values.

12

13 **Acknowledgements**

14 The authors would like to thank the members of the Industrial Systems Engineering Group of
15 Toyohashi University of Technology for their participation in the human judgment evaluation. We
16 also express our appreciation to Yusuke Tsujioka and Yukihiro Takada for their help in the software
17 implementation. We are grateful to Hongcai Wang for translating the data used in the case study and
18 to Fariza Mohamad for her help in the elaboration of the questionnaire. The authors are also indebted
19 to the reviewer and editor of this journal for their helpful comments and suggestions.

Appendix 1. Formal Concept Analysis

Formal Concept Analysis (FCA) can be used to design ontologies from a list of potential classes and their respective attributes. FCA is an analysis technique for information processing based on applied lattice and order theory that can be used to generate taxonomies. In FCA, information is organized in terms of a set of formal objects O , a set of formal attributes A , and a set of binary relations $Y \subseteq O \times A$ containing all pairs $\langle o, a \rangle \in Y$ such that the object $o \in O$ has the attribute $a \in A$. For our purposes, the formal objects represent candidate classes for an ontology.

Information about these three sets is typically summarized by a context table such as the one shown in Fig. 3. In a context table, the objects are listed in the first column and the attributes in the first row of the table.

A formal concept is defined as the pair $\langle O_i, A_i \rangle$ such that:

1. $O_i \subseteq O$, $A_i \subseteq A$.
2. Every object in O_i has every attribute in A_i . Conversely, A_i is the set of attributes shared by all the objects in O_i .
3. For every object $p \in O$ that is not in O_i , there is an attribute in A_i that p does not have.
4. For every attribute in A that is not in A_i , there is an object in O_i that does not have that attribute.

Formal concepts can be partially ordered into a lattice, such that a concept subsumes another concept. Fig. 4 shows the lattice obtained with the data of Fig. 3. Several lattice-construction algorithms are available some of which have been successfully implemented in several applications.
